Problems of using volcanic thermae of the Kurile-Kamehatka Island arc for Power.

Within the Kurile-Kanichatka zone of present-day volcanicity, as well as in many other volcanic regions, there are great resources of thermal power consisting of high temperature volcanic gases, gas vapour jets and various thermal waters. In active volcanic regions (zones of tectonic crushing), the latter come out to the surface of the earth and create numerous big groups of various thermal springs, and among them geysers — these very striking, though rare natural phenomena. However, natural issues of thermal waters to the surface are, as a rule, only an insignificant part of the immense resources in thermal waters concentrated in volcanic regions, which could be, in many cases, brought to the surface by boring.

Sources of thermal power for all these hydrothermal resources are present magmatic foci. However, great thermal anomalies, observed on the surface of active volcanic areas, are mostly not caused by a heat transfer from magmatic foci directly by the rocks (owing to their thermal conductivity) but are a result of the penetration to the surface or into subsurface horizons of rocks of high-temperature volcanic gases steam jets and thermal waters.

In such cases, the created powerful thermal flows, directed towards the surface, are connected with great discharge foci for superheated underground pressure waters.

Data, accumulated during recent years on thermal waters of many volcanic areas, permit to form a more complete idea about their composition, the conditions under which they have been originating and their importance for power utilization.

Within the Kurile Kamehatka volcanic zone, as well as in many other areas of present-day volcanicity (Japan, New Zealand, Iceland

etc.) four principal genetic types of thermal waters one distinguished their comparative characteristics are given on Table 1.

As it may be seen from the table, the main types of thermal waters in volcanic regions substantially differ by the hydrogenispical conditions of their formation, by their gas and ion composition and areas of development.

Among all these types of thermal waters of greatest significance as a source of power are nitric-carbonated thermae bath by their chemical composition, abundant yield and high heat estatest. Due to a high content in them of chemically-agreeave components and owing to a usually lower heat capacity, sulphurous-ambanated and carbonated thermae can not be used effectively for power.

Mitric thermae have, usually, candiderably lesser temperatures and yields.

The most characteristic representatives of nitric-carbonated thermae on Kamchatka are springs in the Goyaer valley and the Passehotha springs, as well as Goriachi Planch (Hot Beach) springs on Kunashir Island (Eurile Islands).

By their issuesit compasition these thermae are sodium-chloride springs with a low general mineralization (up to 4.5 g/l), a higher beans contest (HBO, up to 0.265 g/l) and efficie acid contest (H,51O, to 0.350 g/l) and a low general gas asturation (less than 100 ml/l). (See Table 2).

These waters are formed in abyseal highly reducing environments, under abnormally high geothermal conditions, created by present-day magnetic foci.

In zones of their natural discharge, at a depth of several hundred meters, these waters usually have a temperature considerably above 100°C (up to 200° and more). However, owing to a pressure existing at such a depth, these waters occur there in a liquid state and the conditions of their movement are fully subjected to the fundamental hydrogeological and hydrodynamic laws, characteristic of cedimny pressure waters. The formation of the gastesst-vaposir phase in superheated waters begins only in near-surface conditions. In coming out to the surface, such waters create powerful building quitage and steamwater jets, frequently with a gayeer regime of flow, determined by an insufficient bellow of water to the issue features and consist.

As result of vapour formation, a considerable drop in the temperature of the waters is taking place in near-surface seast, as well-as a general fall in the thornal regime of rocks, in which these waters are circulating.

Analogues of the mentioned waters of the Kurtie-Kamchatka some see thurses of the Valentet region in New Zoaland, which, so to interes, are respectfully being studied and during the last ton years type at a water of power. To the came type of therems belong the flow waters of Estendik region in Icaland, where during recent years missingly. Mr. Same, during the develope.

From the geological paint of view, the region of Possibitian Circums (see the contracting of Basellattia) is attented in an ever of one old trough schedules alled with Quaterning tailes the control part of this trough was subjected during the Quaterning period to a constitutable uplift and formed a big positive structure — the Basellates geometric sange with altitudes exceeding 1000 m. With to continue part is associated the young volcanic activity (Enabelog volcano) in the axial zone of which there are now assestous issues of geotests and volcate jets.

The chief discharge focus of Paushetka thermal waters is situated at the north-western foot of Kambalny range, in the valley of the river Paushetka on a small thermal area (300 × 500 m). We find here several big boiling springs with a total yield of 35 i per assend and two small geysers. The total outflow of thermal water riving to the surface and into alluvial deposits of the valley is estimated to be 100 l/sec.

The first rotary well, put down from the central past of the thormal area to a depth of 800 m, was been with the use of clay floid and a continuous extraction of cases. The initial dismeter of the well was 16", the final —7 ¾". Hydrogeological assuplings to the well were done at certain intervals by the method of experimental vapour-water discharges. Definitions of water and vapour especial-tures were affected by cyclon separators and a calorimeter. Temperature determinations in the well were done by normal marcury and maximum thermometers, as well as by electric thermometers.

The well revealed a thick mass of Quaternary volcanic tuffs, tuff breccia and tuff conglomerates, dacite lavas and, at a depth of 650 m, a mass of Tertiary analystones and aleurolites.

Temperature in the well rose from 100° at the Earth's surface to 180-190°C at a depth of 250-300 m. The most rapid rise in temperature was observed up to a depth of 120 m, the geothermic gradient in this interval being 0.5°/m.

The main inflow of thermal waters, with a composition identical to that of natural springs, was obtained in the well from a depth up to 300 m out of dacite tuffs, in which the water circulation is of a fissure character.

The heat content of the vapour-water mixture in the well was 170-190 big cal/kg, as compared with the heat content of the natural Pauzhetka springs of 140-150 big cal/kg.

Boring of the first Pauzhetka well established the presence within the investigated region of thermal waters suitable, by their heat content and chemical composition, for use as a source of power.

Available geological and hydrogeological data on the investigated region, posselt to assume, that the flow of Paushetha thermal waters to the point of their natural discharge, occurs from the Buell-East, from Kambalay range. Issues of gen-vapuur joks, calcting within the range, are, probably, manifestations of the vapour phase of overheated waters circulating at depth.

Further problems to be solved by investigations and prospecting work, which has been started, should include a greater detailization of the geological structure of the region, the establishment of the most water-abundant zones and the determination of possible resources of thermal waters for the construction of an experimental geothermal power plant.

Discussion

V. VLOBAVETZ signale que les volcanologues ruses se sent intéressés aux secherches géothermiques dans le cens le plus large du terms, non seulement en rapport avec le volcanisme mais aussi avec les phénomènes de la chaleur profuncie du globe. Il présente le premier tome (le seul imprimé actuellement) des publications d'un congrès qui s'est tenu il y a trois ans sur les problèmes de géothermie et d'utilisation de l'énergie géothermique.
